

Dying Young and Frustrated: A study of GPS and CSS sources with the MWA

Joe Callingham

The University of Sydney / CASS

Science at Low Frequencies II, UNM, NM, 3rd December 2015

<http://bit.do/gpscscs>

- › Sampling the spectra above and below the turnover at an unprecedented level.
- › New wide bandwidth backends on the ATCA and VLA.
- › MWA and LOFAR becoming operational.

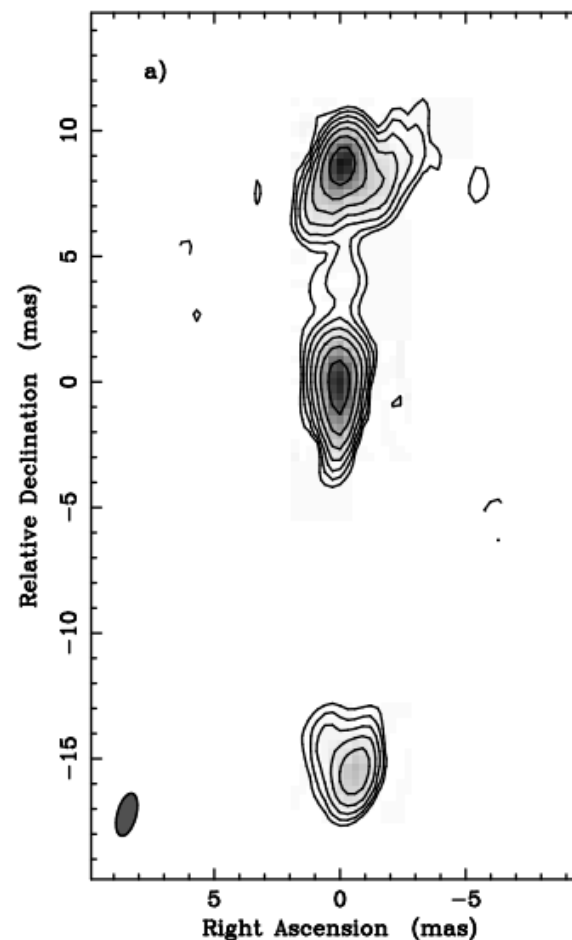

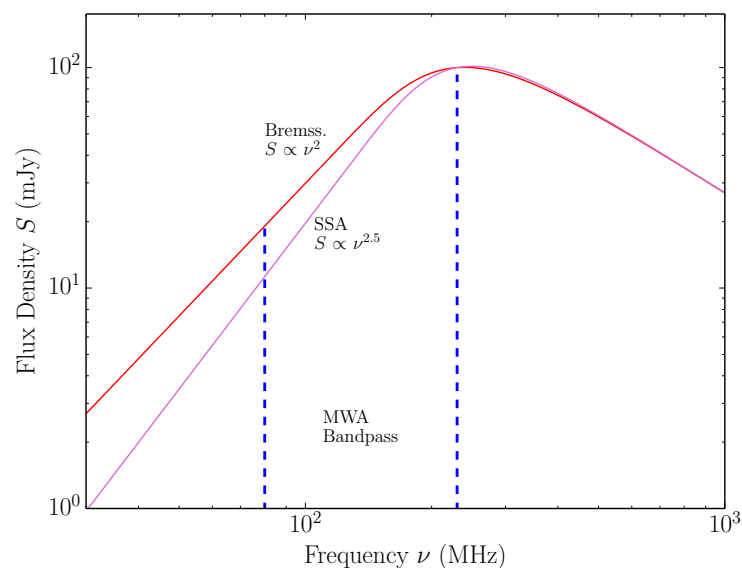

- › GaLactic and Extragalactic All-Sky MWA (GLEAM) survey:
Randall et al. (2015), arXiv:1505.06041
- › Declinations -90° to $+30^\circ$
- › 72-230 MHz, 8 MHz bandwidth
- › Resolution $\sim 3'$ at 72 MHz, $\sim 1'$ at 200 MHz
- › Confusion limited (~ 20 mJy) survey
- › Release \sim early 2016 with $\sim 320,000$ sources.
Commissioning survey released
Hurley-Walker et al. (2015), arXiv:1410.0790

- › Originally empirical classification:
 - Powerful AGN with concave spectra
 - GPS turnover ~ 1 GHz, CSS turnover ~ 150 MHz (?)
 - Small physical sizes. GPS < 1 kpc, CSS $\sim 1 - 10$ kpc
 - Hosts vary - quasars, radio galaxies and Seyferts

Why Study CSS/GPS Sources?

- › Unique view of early stages of AGN activity. Probe of environment to tens pc scale.
- › How many sources go from birth to A team sources (Cyg A, Her A etc)?
- › Are they confined to small spatial scales due to ‘youth’ or ‘frustrated’ or **both**?
- › Cause of the turnover in spectrum? Vital for accurate evolutionary models

Peck et al. 1999; Kameno et al. 2000; Marr et al. 2001; Orienti & Dallacasa 2008; Tremblay et al. 2008, Marr et al. 2014; Tingay et al. 2015

Inhomogeneous free-free model (Bicknell et al. 1997, Begelman 1999)

Synchrotron self-absorption (SSA) model (Kellermann 1966)

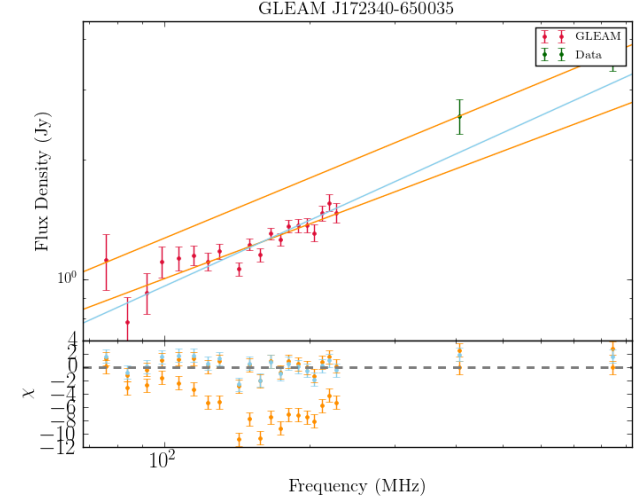

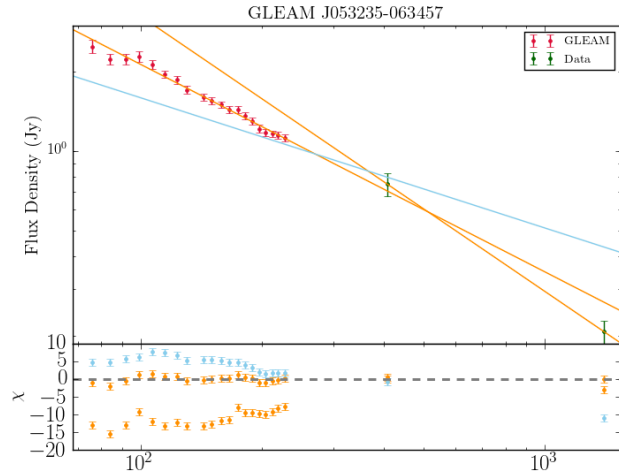

Prediction of 2.5 slope – never seen

- › Low frequency data has a gradient of ~ 2.5 – **steepest known**. Spectral width ~ 0.6 decade of freq. – **smallest known**.
- › Test bed for models of GPS/ CSS spectra.
- › ~ 120 mas scale, 1000 pc

Why Bayes?

Aesthetics:

- › Philosophy – accepting a theory rather than rejecting a hypothesis.
- › Chi-squared evaluates the significance of the *mismatch* between theory and experiment, not whether the hypothesis is true.
- › Rigorous theoretical framework

Positives - Practical:

- › Full PDFs for each model parameter
- › Prior knowledge can be used to get a more accurate result and place physical constraints.
- › Can deal with non-Gaussian uncertainties (e.g. calibration errors)
- › Marginalise over nuisance parameters (e.g. noise floor.)
- › Objective model selection more robust than reduced chi-squared.
- › Less likely to get stuck in a local minimum due to implementation.
- › Hyperparameters

Negatives:

- › Less 'natural' to think about – integrals, baggage of another statistical language etc.
- › More computationally expensive
- › In simple cases, often converges to the same parameter values as less computationally expensive methods do.
- › More difficult and time consuming to code.
- › Can be influenced by prior knowledge.
